

L'Hôpital's (Selection) Rule

An Empirical Bayes Application to French Hospitals

Fu Zixuan

Supervised by Prof. Thierry Magnac

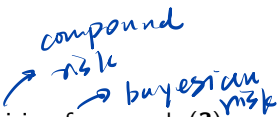

July 2, 2024

Literature: Measuring efficiency of individual units

- ▶ *Productivity/Efficiency*: Factories, Schools, Hospitals etc.
- ▶ *Ownership*: Public (Teaching, Ordinary) vs. Private (For profit, Non-profit).
- ▶ *Methodology*: Following ?, we use the *conditional input demand function*. The less input is needed to produce the same amount of output, the more efficient the hospital is. [▶ Reasons](#)

simple specification

Literature: Invidious decision

- ▶ *League table mentality*: Ranking & Selection.(?)
 - ▶ *Noisy estimates*: e.g. estimated fixed effect $\hat{\theta}_i$. (??)
 - ▶ *Compound Decision/ Empirical Bayesian*: Compound decision framework (?),
(Non-parametric) Estimation of the prior distribution of θ_i . (??)
- 

Questions

- ▶ Out of the top 20% hospitals in France in terms of labor employment efficiency, how many of them are public hospitals/private hospitals?
- ▶ Take fair value
What would be the selection outcome if I want to control the number of mistakes that I make?
- ▶ Does different selection rule produce different results? And to what degree?

Recap

later.

1. **Estimate the efficiency** with input demand function.

– LHS X : Labor input (number of full time equivalent nurses).

– RHS Y : Hospital output (e.g., inpatient/outpatient stays, medical sessions).

$$\log(x_{it,\text{nurses}}) = \log(y_{it,\text{output}})\beta + \theta_i + \varepsilon_{it} \quad \text{where} \quad \varepsilon_{it} \sim \mathcal{N}(0, \sigma_i^2)$$

↓ the more

2. **Estimate the prior distribution G of θ_i** with nonparametric maximum likelihood estimator (NPMLE).

3. **Select the 20% most efficient hospitals.**

first

- ▶ Hospitals differ not only in efficiency but also in the mix of services they provide.
- ▶ Teaching hospitals may be innately very different from others (training, research).

▶ Appendix

Compound Decision Framework

Observe:

a vector of \wedge

$$\hat{\boldsymbol{\theta}} = (\hat{\theta}_1, \dots, \hat{\theta}_n)$$

where $\hat{\theta}_i | \theta_i \sim P_{\theta_i}$

Decision:

$$\delta(\hat{\boldsymbol{\theta}}) = (\delta_1(\hat{\boldsymbol{\theta}}), \dots, \delta_n(\hat{\boldsymbol{\theta}}))$$

a vector of decisions

why Compound Loss and Risk

Loss:

loss is a sum of individual lvs

$$\underline{L_n(\theta, \delta(\hat{\theta}))} = \sum_{i=1}^n \underline{L(\theta_i, \delta_i(\hat{\theta}))}.$$

Risk (Expectation of loss):

risk function

$$R_n(\theta, \delta(\hat{\theta})) = \mathbb{E}[L_n(\theta, \delta(\hat{\theta}))]$$

$$= \frac{1}{n} \sum_{i=1}^n \mathbb{E}_{\theta_i | \hat{\theta}_i} [L(\theta_i, \delta_i(\hat{\theta}))] \quad \text{Separable decision rule } \delta$$

$$= \frac{1}{n} \sum_{i=1}^n \int L(\theta_i, \delta_i(\hat{\theta}_i)) dP_{\theta_i}(\hat{\theta}_i)$$
$$= \iint L(\theta_i, \delta(\hat{\theta}_i)) dP_{\theta_i}(\hat{\theta}_i) dG_n(\theta)$$

where $G_n(\theta)$ is the empirical distribution (Frequentist View) of $\theta \sim G$.

→ Bayesian view: replace G_n by a distribution G . → Empirical Bayes: Estimate the G .

Compound decision and Empirical Bayes

by assuming a distribution G

Estimate G

? established the nonparametric maximum likelihood estimator (NPMLE)

$$\hat{G} = \arg \min_{G \in \mathcal{G}} \left\{ - \sum_{i=1}^n \log \underbrace{g(\hat{\theta}_i)}_{\text{prob./likelihood of}} \mid g(\hat{\theta}_i) = \int \mathbb{P}(\hat{\theta}_i | \theta) dG(\theta) \right\}$$

where $\mathbb{P}(\hat{\theta}_i | \theta)$ is the probability density function of $\hat{\theta}_i$ conditional on the true parameter $\theta \longrightarrow$
 $g(\hat{\theta}_i)$ is the marginal pdf of $\hat{\theta}_i$.

Estimate G

[fragile] This is an **infinite-dimensional** convex optimization problem with a strictly convex objective subject to linear constraints.

$$\min_{f=dG} \left\{ - \sum_i \log g(y_i) \middle| g(y_i) = T(f), K(f) = 1, \forall i \right\}$$

where $T(f) = \int \mathbb{P}(y_i|\theta) f d\theta$ and $K(f) = \int f d\theta$.

Consistency is proven by ?. Efficient computation method introduced by ?. Implemented with MOSEK+ created by ?.

Having e.

The Selection Task

define was spec to the selection

- ▶ Select the bottom 20% (the smaller the θ_i , the more efficient) of the true θ_i . Since we assume that $\theta_i \sim G$, those i whose $\theta_i < G^{-1}(0.2)$
- ▶ Control the overall false discovery rate at 20%,

20%

$$\frac{\mathbb{E}_G [\mathbb{I} \{ \theta_i > \theta_\alpha, \delta_i = 1 \}]}{\mathbb{E}_G [\delta_i]} \leq \gamma$$

1. Nominator: Selected but whose true value $> G^{-1}(0.2)$.
2. Denominator: Selected.

Problem Formulation

The **loss** function is *non selected* *false*.

$$L(\delta, \theta) = \sum h_i(1 - \delta_i) + \tau_1 \left(\sum (1 - h_i)\delta_i - \gamma\delta_i \right) + \tau_2 \left(\sum \delta_i - \alpha n \right)$$

where $h_i = 1 \{ \theta_i < \theta_\alpha = G^{-1}(\alpha) \}$. h_i is an indicator of whether the true value belong to the set. δ_i is an indicator of whether i is being selected. Therefore, the **problem** is to find δ such that

Bayesian NBIC

$$\begin{aligned} \min_{\delta} \quad & \mathbb{E}_G \mathbb{E}_{\theta|\hat{\theta}} [L(\delta, \theta)] \\ = & \mathbb{E}_G \sum \mathbb{E}(h_i)(1 - \delta_i) + \tau_1 \left(\sum (1 - \mathbb{E}(h_i))\delta_i - \gamma\delta_i \right) \\ & + \tau_2 \left(\sum \delta_i - \alpha n \right) \\ = & \mathbb{E}_G \sum v_\alpha(\hat{\theta})(1 - \delta_i) + \tau_1 \left(\sum (1 - v_\alpha(\hat{\theta}))\delta_i - \gamma\delta_i \right) + \tau_2 \left(\sum \delta_i - \alpha n \right) \end{aligned}$$

where $v_\alpha(\hat{\theta}) = \mathbb{P}(\theta < \theta_\alpha | \hat{\theta})$ is the **posterior tail probability**.

Derive tail probability v_α

Pick hospital i whose true efficiency value is θ_i , which we don't observe. We only observe a sequence of Y_{it} where

$$Y_{it} = \theta_i + \varepsilon_{it} \quad \varepsilon_{it} \sim \mathcal{N}(0, \sigma_i^2) \quad (\theta_i, \sigma_i^2) \sim G$$

Neither θ_i nor σ_i^2 is known. But the sufficient statistics are

$$Y_i = \frac{1}{T_i} \sum_{t=1}^{T_i} Y_{it} \quad \text{where} \quad Y_i | \theta_i, \sigma_i^2 \sim \mathcal{N}(\theta_i, \sigma_i^2 / T_i)$$

$$S_i = \frac{1}{T_i - 1} \sum_{t=1}^{T_i} (Y_{it} - Y_i)^2 \quad \text{where} \quad S_i | \sigma_i^2 \sim \Gamma(r_i = (T_i - 1)/2, 2\sigma_i^2 / (T_i - 1))$$

In our input demand function specification, we have $Y_{it} = \log(x_{it}) - \beta \log(y_{it})$. [► Appendix](#)

TP and Constraints

Given the two sufficient statistics, the posterior tail probability is

$$\begin{aligned} v_{\alpha}(\hat{\theta}_i) &= v_{\alpha}(Y_i, S_i) \\ &= P(\theta_i < \theta_{\alpha} | Y_i, S_i) \\ &= \frac{\int_{-\infty}^{\theta_{\alpha}} \Gamma(s_i | r_i, \sigma_i^2) f(y_i | \theta_i, \sigma_i^2) dG(\theta_i, \sigma_i^2)}{\int_{-\infty}^{\infty} \Gamma(s_i | r_i, \sigma_i^2) f(y_i | \theta_i, \sigma_i^2) dG(\theta_i, \sigma_i^2)} \end{aligned}$$

We want to find a cutoff λ such that both constraints are satisfied ³:

- Capacity: $\int \int P(v_{\alpha}(Y_i, S_i) > \lambda) dG(\theta_i, \sigma_i^2) \leq \alpha$
- FDR: $\int \int \frac{E[1\{v_{\alpha}(Y_i, S_i) > \lambda\}(1 - v_{\alpha}(Y_i, S_i))]}{E[1\{v_{\alpha}(Y_i, S_i) > \lambda\}]} dG(\theta_i, \sigma_i^2) \leq \gamma$

³Relaxed discrete optimization problem, following (?)

Recap

1. We have a $N \times T$ panel. Y_{it} is an observation of hospital i 's efficiency term θ_i at time t . Say $Y_{it}|\theta_i, \sigma_i \sim \mathcal{N}(\theta_i, \sigma_i^2)$.
2. Given a panel of Y_{it} , perform NPMLE to get an estimate of $G(\theta)$ or $G(\theta, \sigma^2)$.
3. Given the estimated prior G , derive the explicit form of posterior tail probability $v_\alpha(Y_i, S_i)$ and the two constraints.
4. Solve the selection problem and find the optimal δ^*

$$\min_{\delta} \mathbb{E}_G \sum v_\alpha(\hat{\theta})(1 - \delta_i) + \tau_1 \left(\sum (1 - v_\alpha(\hat{\theta}))\delta_i - \gamma\delta_i \right) + \tau_2 \left(\sum \delta_i - \alpha n \right)$$

5. The decision rule is defined by the cutoff λ

$$\delta^*(y_i, s_i) = 1 \{v_\alpha(y_i, s_i) > \lambda^*\}$$

The estimated \hat{G}

Case 1: $G(\theta, \sigma)$ for $v_\alpha(Y_i, S_i)$

Case 2: $G(\theta)$ for $v_\alpha(Y_i)$

The estimated \hat{G}

Case 1: $G(\theta, \sigma)$ for $v_\alpha(Y_i, S_i)$

Case 2: $G(\theta)$ for $v_\alpha(Y_i)$

$G(\theta, \sigma)$: Posterior Tail probability (0.2,0.2)

$G(\theta)$: Posterior Tail probability (0.2,0.2)

$G(\theta)$: Posterior Tail probability (0.2,0.1)

"Face value"

Fixed effect estimation

Assume that $\mathbb{E}[\varepsilon_{it}|\theta_i, x_{i1}, \dots, x_{i,t-1}] = 0$.

First Difference GMM: use lagged level as instruments for current difference

$$\mathbb{E}[x_{i,t-2}(\Delta y_{it} - \beta \Delta x_{it})]$$

System GMM: use lagged difference as instruments for current levels

$$\mathbb{E}[\Delta x_{i,t-1}(y_{it} - \beta x_{it})] \quad \text{if} \quad \mathbb{E}[\Delta x_{i,t-1}(\theta_i + \varepsilon_{i,t})] = 0$$

Conclusion

Another point

- ▶ Whether to control for **False discovery rate** → Control for FDR shrinks the selection set.
- ▶ Whether to assume known σ_i makes a difference → Assume unknown σ_i makes the FDR constraints bind, thus less selected than assuming σ_i known.
- ▶ Private (FP and NP) hospitals are indeed more "efficient" → Caution.

intuitive
however

$$\frac{10.}{4}$$

Limitation

Inter

- Interpretation of the θ_i : The Schmidt and Sickles/Pitt and Lee models treat all time invariant effects as inefficiency. ? treats time invariant components as only unobserved heterogeneity.
- Specification, endogeneity, normality assumption on ε_{it} .etc. [► Next](#)

Conditional Input Demand Function

In standard microeconomics, the profit maximization problem is

$$\max_{\vec{y}} \sum k_i y_i - \sum p_i x_i \quad \text{subject to} \quad f_i(x_1, x_2, \dots, x_n) = y_i$$

where p_i is the price of input i and f is the cost function.

The cost minimization problem is thus

$$\min_{\vec{x}} \sum p_i x_i \quad \text{subject to} \quad f_i(x_1, x_2, \dots, x_n) = y_i$$

Thus, the factor demand function/correspondence is

$$x_i = x_i(p_1, p_2, \dots, p_n, y_1, y_2, \dots, y_m)$$

Input demand function vs Production function

- ▶ We can remain agnostic as to the nature of the appropriate formula for the aggregation of outputs and use as many different products as desired.
- ▶ When input prices have low variability. Conditional factor demand can be estimated without information on input prices. Even if we add prices, due a lack of variability, the price parameters will be poorly estimated.
- ▶ From $x_i = x_i(p_1, p_2, \dots, p_n, y_1, y_2, \dots, y_m)$, we do not need to observe a complete list of inputs. But we do need to observe all input prices (can be ignored if almost no variability) and all outputs. While in the production function, it is the other way around (need to observe all inputs). Since, in our case, output is more *observable* than input (because capital is not easily observed), this approach is preferred.

Panel data Estimator

- ▶ Strict exogeneity: Within Group/First Difference

$$E[\epsilon_{it}|x_{i1}, \dots, x_{iT}, \theta_i] = 0$$

- ▶ Relaxed: First Difference GMM (?), System GMM (??).

$$E[\epsilon_{it}|x_{i1}, \dots, x_{it-p}, \theta_i] = 0$$

Issues: Weak instruments (?) and the proliferation of instruments (?).

$$\mathbb{E}[\Delta x_{i,t-1}(y_{it} - \beta x_{it})] \quad \text{if} \quad \mathbb{E}[\Delta x_{i,t-1}(\theta_i + \varepsilon_{i,t})] = 0$$

NPMLE Computation Methods

The primal problem:

$$\min_{f=dG} \left\{ - \sum_i \log g(y_i) \middle| g(y_i) = T(f), K(f) = 1, \forall i \right\}$$

where $T(f) = \int p(y_i|\theta) f d\theta$ and $K(f) = \int f d\theta$.

Discretize the support:

$$\min_{f=dG} \left\{ - \sum_i \log g(y_i) \middle| g = Af, 1^T f = 1 \right\}$$

where $A_{ij} = p(y_i|\theta_j)$ and $f = (f(\theta_1), f(\theta_2), \dots, f(\theta_m))$.

The dual problem:

$$\max_{\lambda, \mu} \left\{ \sum_i \log \lambda_1(i) \middle| A^T \lambda_1 < \lambda_2 1, (\lambda_1 > 0) \right\}$$

Normality assumption on ε_{it}

Estimate the fixed effect θ_i by

$$\hat{\theta}_i = \frac{1}{T} \sum (\theta_i + \varepsilon_{it} + x_{it}(\beta - \hat{\beta}))$$
$$\xrightarrow{N \rightarrow \infty} \theta_i + \frac{1}{T} \sum_t \varepsilon_{it}$$

When T is relatively small (or even fixed), can't use central limit theorem to claim that $\hat{\theta}_i \xrightarrow{d} \mathcal{N}(\theta_i, \frac{\sigma_i^2}{T})$. \longrightarrow Assume that $\varepsilon_{it} \sim \mathcal{N}(0, \sigma_i^2)$.
